POST-FLIGHT SURVEYS
OF
ENGELMANN SPRUCE BEETLE INFESTATIONS
IN
NORTHERN IDAHO AND WESTERN MONTANA^{1/}
1953

A large number of Engelmann spruce stands were surveyed by this laboratory during the summer and fall of 1953 to fulfill the need for information on the post-flight Engelmann spruce beetle infestation. The surveys were designed to obtain data to meet three specific needs: 1) to up-date pre-flight data from 1952 or early 1953 surveys, 2) provide basic data on known but unappraised outbreaks and, 3) measure the results of control. To meet the various requirements, different types of surveys were made. Where the areas had been previously surveyed and the data were adequate for sale preparation, post-flight surveys were made to measure the change in status of the infestation. The data obtained could then be applied to previous survey information to show the current loss. These surveys were called "ratio" surveys because they were designed to show the ratio of trees attacked in 1953 to trees attacked in 1952. In the following table these ratios are shown for trees and for basal area. The ratio of change on a tree to tree basis is a good measure of the entomological aspects of the infestation. Because beetle attacked trees are normally of larger than average diameter, a ratio of change on a basal area basis gives a figure that is nearer to a comparison of the actual volume killed than the tree to tree figure. A better comparison would, of course, be on volume to volume basis but to compile such data within the short period available is not practical.

Where no information other than detection survey data was available, reconnaissance surveys were made. Reconnaissance surveys provided the same information as ratio surveys and in addition supplied the necessary data on the green residual stand.

In the following tables the acreage figure given is usually of surveyed spruce type averaging 3 M ft. bm. per acre or over. Type having less than 3 M bd. ft. per acre is not considered to be heavily enough stocked to maintain a serious infestation and therefore is not considered "host type".
